HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Evaluation of a musculoskeletal finite element model of the foot

Antoine Perrier, Vincent Luboz, Marek Bucki, Francis Cannard, Nicolas Vuillerme, Yohan Payan

This work aims at developing a patient-specific Finite Element (FE) model of the foot in the context of pressure ulcer prevention. Starting from our previous model {1} we propose here to improve the realism of the anatomy by introducing all the detailed bony structures, ligaments and muscles segmented from the CT and MRI exams of the same patient. The model has been developed using the 3D biomechanical simulation platform Artisynth (artisynth.org). It includes 30 bones modeled as articulated rigid-bodies connected with cables that simulate the 210 segmented ligaments in their actual positions and therefore define the articulations. The aponeurosis is modeled with five parallel multipoint ligaments. A set of 15 extrinsic and intrinsic muscles based on linear axial muscle activation law is anatomically positioned in order to allow a natural movement of the foot.

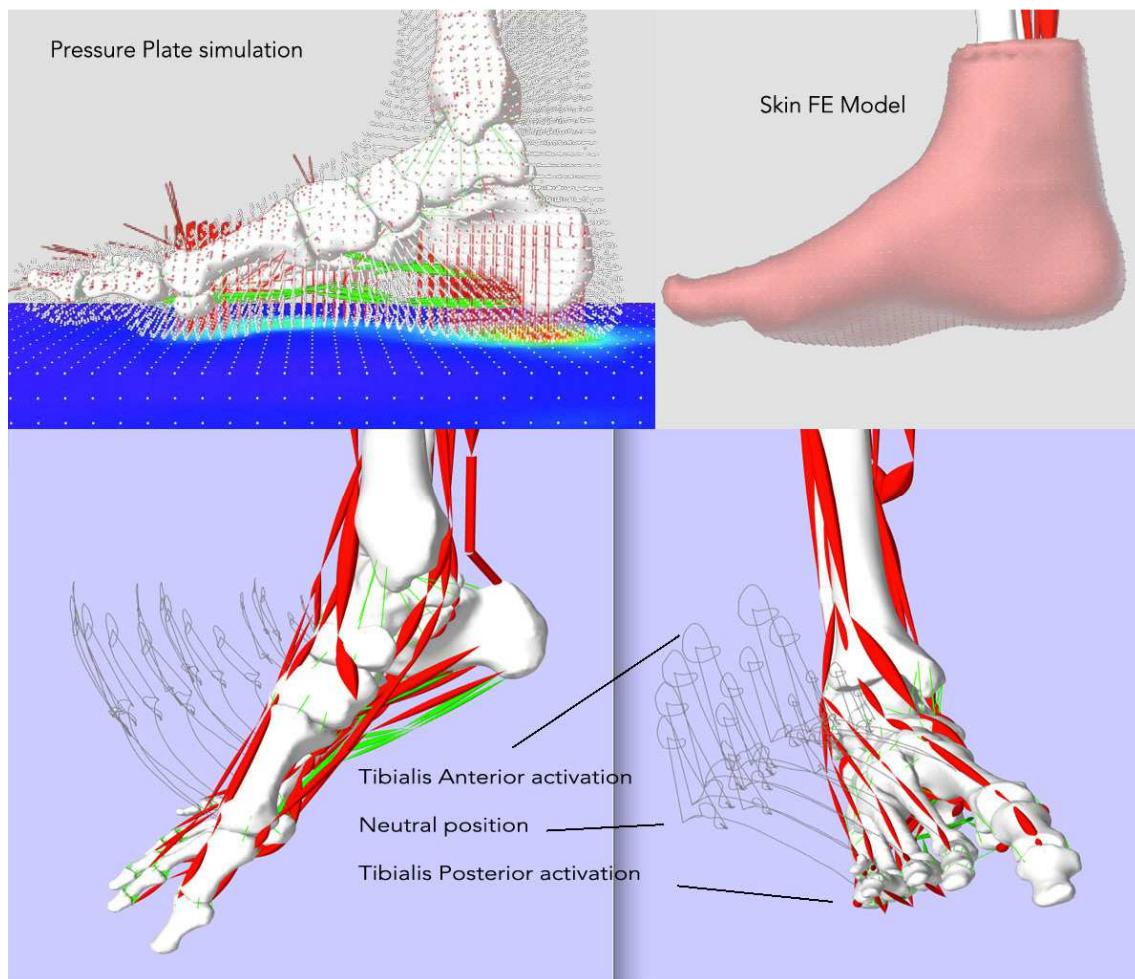

A FE mesh of the soft tissue was created by applying an automatic FE mesh generator {2} to the surfaces resulting from MRI segmentation. The FE mesh has 95883 elements and 56806 nodes. Three soft tissue layers with Neo Hookean materials (Young moduli, Poisson Ratio) were created to represent a 1mm skin layer (200, 0.485), the fat (30, 0.49) and muscle (60, 0.495) tissues.

The foot model was evaluated by comparing its simulations with the pressure mat collected with the patient standing onto a Zebris FDM platform (www.zebris.de). For this, the patient weight was applied onto the foot model put in contact with an horizontal plate (figure). Another evaluation of the model aimed at comparing the kinematics of the model resulting from simulated muscle activations with an actual 3D motion analysis of the patient foot {3} coupled with an EMG monitoring of the tibialis posterior, tibialis anterior, soleus, medial gastrocnemius, lateral gastrocnemius and peroneus muscles. Globally, this new version of the foot model provides realistic simulations in both static and dynamic frameworks. In addition to its use for pressure ulcer prevention, it could become relevant for the simulation of neuro-orthopedic surgical interventions, orthotic devices analysis or educational purposes.
